HSA-FREE FORMULATIONS OF INTERFERON-BETA

CROSS-REFERENCE TO RELATED APPLICATION

This application claims the benefit of U.S. Provisional Application Serial No.

_____, filed October 18, 2001, entitled "HSA-Free Formulations of

Interferon-Beta," and U.S. Provisional Application Serial No. 60/282,614, filed April 9,

5   2001, each of which is herein incorporated by reference in its entirety.

FIELD OF THE INVENTION

The invention relates generally to pharmaceutical compositions, more particularly

to stabilized formulations of interferon-β that are free of human serum albumin as an

10   added pharmaceutical excipient.

BACKGROUND OF THE INVENTION

The interferons are a family of glycoproteins whose secretion from cells is

induced by a number of signals including viruses, double-stranded RNAs, other

15   polynucleotides, antigens, and mitogens. Interferons exhibit multiple biological

activities, including antiviral, antiproliferative, and immunomodulatory activities. At least

three distinct types of human interferons, α, β, and γ, have been distinguished based on a

number of factors, including anti-viral and anti-proliferative activities.

Interferon-β (IFN-β) is the first identified effective treatment for those with

20   multiple sclerosis (MS), and has been demonstrated to reduce the number of attacks

suffered by patients with relapsing and remitting MS, and secondary progressive MS.

IFN-β compositions are also useful in the treatment of hepatitis B and C infections.

As with all protein-based pharmaceuticals, one major obstacle that must be overcome in the use of IFN-β as a therapeutic agent is the loss of pharmaceutical utility that can result from its instability in pharmaceutical formulations. Physical instabilities that threaten polypeptide activity and efficacy in pharmaceutical formulations include denaturation and formation of soluble and insoluble aggregates, while chemical instabilities include hydrolysis, imide formation, oxidation, racemization, and deamidation. Some of these changes are known to lead to the loss or reduction of the pharmaceutical activity of the protein of interest. In other cases, the precise effects of these changes are unknown, but the resulting degradative products are still considered to be pharmaceutically unacceptable due to the potential for undesirable side effects.

The stabilization of polypeptides in pharmaceutical compositions remains an area in which trial and error plays a major role (reviewed by Wang (1999) *Int. J. Pharm.* 185:129-188; Wang and Hanson (1988) *J. Parenteral Sci. Tech.* 42:S3-S26). Excipients that are added to polypeptide pharmaceutical formulations to increase their stability include buffers, sugars, surfactants, amino acids, polyethylene glycols, and polymers, but the stabilizing effects of these chemical additives vary depending on the protein.

One of the major obstacles to preparing stabilized IFN-β pharmaceutical formulations has been the poor solubility of the IFN-β molecule. Current formulations employ the use of HSA as a solubility-enhancing agent for IFN-β. However, the use of HSA has drawbacks. HSA is a product of human blood and must therefore be harvested from human subjects. While steps are taken to reduce the risk, the use of human blood products such as HSA carries with it the potential introduction of human viruses such as HIV and HCV. The introduction of HSA into the formulation also interferes with the ability to properly determine the stability of IFN-β in the formulation. This is because HSA and IFN-β are both proteins, and the HSA interferes with some of the IFN-β stability-indicating assays.

Furthermore, IFN-β is a protein that exhibits aggregate formation when prepared in pharmaceutical compositions, and hence the amount of this protein in its monomeric biologically active state is compromised during storage of these compositions. Aggregate formation by a polypeptide such as IFN-β during storage of a pharmaceutical

-2-

composition can adversely affect biological activity of that polypeptide, resulting in loss of therapeutic efficacy of the pharmaceutical composition. Furthermore, aggregate formation may cause other problems such as blockage of tubing, membranes, or pumps when the IFN-β pharmaceutical composition is administered using an infusion system.

5   In addition, injection of a pharmaceutical composition comprising the aggregated form of a protein has the potential for generating an immunogenic reaction to the aggregated protein.

Consequently, there is a need for additional IFN-β pharmaceutical compositions comprising physiologically compatible stabilizers that improve the solubility of this

10   protein and stabilize the protein against aggregate formation, thereby enhancing their pharmaceutical utility.

SUMMARY OF THE INVENTION

Compositions comprising interferon-beta (IFN-β) as a therapeutically active

15   component and methods useful in their preparation are provided. The compositions are stabilized pharmaceutical compositions that are free of human serum albumin (HSA) as a pharmaceutical excipient and which comprise substantially monomeric IFN-β solubilized in a low-ionic-strength formulation. The low-ionic-strength formulation is a solution that comprises a buffer in an amount sufficient to maintain the composition at a specified pH

20   plus or minus 0.5 units, where the specified pH is about 3.0 to about 5.0, and which has an ionic strength of not greater than about 60 mM. . A non-ionic tonicifying agent is incorporated into the pharmaceutical compositions to render the compositions isotonic, where the tonicifying agent is a carbohydrate. Methods for increasing solubility of IFN-β in pharmaceutical compositions, and for increasing the amount of monomeric IFN-β in

25   these compositions, without the use of human serum albumin are also provided.

DETAILED DESCRIPTION OF THE INVENTION

The present invention is directed to stabilized pharmaceutical compositions that comprise interferon-beta (IFN-β) and methods for their preparation. These compositions are prepared in the absence of human serum albumin (HSA), and are thus free of this pharmaceutical excipient. Such compositions are referred to herein as "HSA-free" IFN-β pharmaceutical compositions. The compositions comprise substantially monomeric IFN-β that is solubilized in a low-ionic-strength formulation.. By "low-ionic-strength" formulation is intended a solution that comprises a buffer in an amount that is sufficient

to maintain the pH of the pharmaceutical composition within plus or minus 0.5 units of a specified pH, and which has an ionic strength that is not greater than about 60 mM. By "ionic strength" is intended the standard chemical definition as applied to a solution, where ionic strength of a solution is equal to $\frac{1}{2} \Sigma c_i z_i^2$, in which c is the concentration

5   and z is the charge. The buffer is present in the low-ionic-strength formulation at a concentration of about 1 mM to about 30 mM, preferably about 2 mM to about 25 mM, more preferably about 2 mM to about 20 mM, even more preferably about 2 mM to about 10 mM, still more preferably about 2 mM to about 5 mM. Thus, in some embodiments, the low-ionic-strength formulation comprises a buffer at a concentration of about 2 mM

10   to about 10 mM, about 2 mM to about 7 mM, about 2 mM to about 5 mM, about 2 mM, about 3 mM, about 4 mM, or about 5 mM. Suitable buffers that can be used to prepare the low-ionic-strength formulation in which the IFN-β is solubilized include, but are not limited to, glycine, aspartic acid, sodium succinate, citrate, formate, acetate, glutamic acid, histidine, imidazole, and phosphate, preferably glycine, aspartic acid, and sodium

15   succinate, more preferably glycine and aspartic acid.

Preferably the low-ionic-strength formulation has an ionic strength that is not greater than about 60 mM, more preferably not greater than about 40 mM, still more preferably not greater than about 20 mM. In some embodiments, the ionic strength of the formulation is solely determined by the buffer concentration, and hence the formulation

20   does not have additional ionic species, such as sodium chloride, potassium chloride, magnesium chloride, ammonium salt, and the like, contributing to its ionic strength.

Use of a low-ionic-strength formulation that is a solution comprising a buffer at a concentration of about 1 mM to about 30 mM, preferably at about 2 mM to about 5 mM, provides for the preparation of stabilized IFN-β pharmaceutical compositions that have a

25   pH of about 3.0 to about 5.0, preferably about 3.0 to about 4.5, more preferably about 3.0 to about 4.0, still more preferably about 3.5 to about 4.0, most preferably about 4.0, depending upon the particular buffer used. Thus, when the buffer is glycine, the pH of the composition is about 3.0 to about 3.5, preferably about 3.0. When the buffer is aspartic acid, the pH of the composition is about 3.5 to about 4.5, preferably about 4.0.

-6-

When the buffer is sodium succinate, the pH of the composition is about 4.5 to about 5.0, preferably about 5.0.

By maintaining the pH of the IFN-β pharmaceutical compositions of the invention within the range of about pH 3.0 to about pH 5.0 it is possible to increase the solubility of

5 IFN-β in these compositions beyond that normally possible in the absence of the use of human serum albumin. Furthermore, by incorporating IFN-ß into a low-ionic-strength formulation as defined herein it is possible to prepare pharmaceutical compositions that comprise substantially monomeric IFN-β. By "substantially monomeric" is intended that the majority of IFN-β (by weight) present in the composition is in its monomeric form

10 rather than an aggregated form. By "aggregated" is intended a physical interaction between the polypeptide molecules that results in the formation of multimers (dimers, trimers, etc.) that may remain soluble or that may precipitate out of solution. The monomeric form of the IFN-β polypeptide remains soluble, and hence is said to be "solubilized" in the low-ionic-strength formulation or pharmaceutical compositions of the

15 present invention. The percentage (by weight) of IFN-β that is in its monomeric form in the HSA-free compositions of the invention may vary from 80% or greater. The present invention thus provides HSA-free, IFN-β pharmaceutical compositions that comprise at least about 80% of the IFN-β in its monomeric form, as opposed to its aggregated form, preferably at least about 85%, more preferably at least about 90%, still more preferably at

20 least about 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% or more of the IFN-β in its monomeric form.

In some embodiments of the invention, the HSA-free IFN-β pharmaceutical compositions further comprise a non-ionic tonicifying agent in an amount sufficient to render the compositions isotonic with body fluids. The compositions can be made

25 isotonic with a number of non-ionic tonicity modifying agents ordinarily known to those in the art. These are typically carbohydrates of various classifications (see, for example, Voet and Voet (1990) *Biochemistry* (John Wiley & Sons, New York). Monosaccharides classified as aldoses such as glucose, mannose, arabinose, and ribose, as well as those classified as ketoses such as fructose, sorbose, and xylulose can be used as non-ionic

tonicifying agents in the present invention. Disaccharides such a sucrose, maltose, trehalose, and lactose can also be used. In addition, alditols (acyclic polyhydroxy alcohols) such as glycerol, mannitol, xylitol, and sorbitol are non-ionic tonicifying agents useful in the present invention. The most preferred non-ionic tonicifying agents are trehalose, sucrose, and mannitol, or a combination thereof. The non-ionic tonicifying agent is added in an amount sufficient to render the formulation isotonic with body fluids. When incorporated into the HSA-free IFN-β pharmaceutical compositions, the non-ionic tonicifying agent is present at a concentration of about 1% to about 10%, depending upon the agent used. Thus, in one embodiment, the non-ionic tonicifying agent is trehalose or sucrose at a concentration of about 8% to about 10%, preferably about 9% by weight per volume, and preferably is trehalose at this concentration. In another embodiment, the non-ionic tonicifying agent is mannitol at a concentration of about 4% to about 6%, preferably about 5% by weight per volume. In other embodiments, the non-ionic tonicifying agent is a combination of trehalose and mannitol, or sucrose and mannitol, where the trehalose and sucrose are present at a concentration of about 1% by weight per volume and the mannitol is present at a concentration of about 3% to about 5% by weight per volume, preferably about 4.6% by weight per volume.

The HSA-free IFN-β pharmaceutical compositions of the invention encompass liquid compositions and dried forms thereof. For purposes of the present invention, the term "liquid" with regard to pharmaceutical compositions or formulations is intended to include the term "aqueous", and includes liquid formulations that are frozen. By "dried form" is intended the liquid pharmaceutical composition or formulation is dried either by freeze drying (i.e., lyophilization; see, for example, Williams and Polli (1984) *J. Parenteral Sci. Technol. 38*:48-59), spray drying (see Masters (1991) in *Spray-Drying Handbook* (5th ed; Longman Scientific and Technical, Essez, U.K.), pp. 491-676; Broadhead *et al.* (1992) *Drug Devel. Ind. Pharm. 18*:1169-1206; and Mumenthaler *et al.* (1994) *Pharm. Res. 11*:12-20), or air drying (Carpenter and Crowe (1988) *Cryobiology 25*:459-470; and Roser (1991) *Biopharm. 4*:47-53). The term "lyophilize" with regard to IFN-β pharmaceutical formulations is intended to refer to rapid freeze drying under reduced pressure of a plurality of vials, each containing a unit dose of the interferon

-8-

formulation of the present invention therein. Lyophilizers, which perform the above described lyophilization, are commercially available and readily operable by those skilled in the art. In one embodiment of the present invention, the liquid composition is prepared as a lyophilized composition.

In other embodiments of the invention, the HSA-free IFN-β pharmaceutical compositions of the invention can be prepared in a form that is suitable for pulmonary delivery and administering the preparation to the subject via pulmonary inhalation. By "pulmonary inhalation" is intended the pharmaceutical composition is directly administered to the lung by delivering the composition in an aerosol or other suitable preparation from a delivery device into the oral cavity of the subject as the subject inhales through the oral cavity. By "aerosol" is intended a suspension of solid or liquid particles in flowing air or other physiologically acceptable gas stream. Other suitable preparations include, but are not limited to, mist, vapor, or spray preparations so long as the particles comprising the protein composition are delivered in a size range consistent with that described for a dry powder form of the pharmaceutical composition as defined below. Pulmonary inhalation could also be accomplished by other suitable methods known to those skilled in the art. These may include liquid instillation using a suitable device or other such methods. Pulmonary inhalation results in deposition of the inhaled protein composition in the alveoli of the subject's lungs. Once deposited, the protein may be absorbed, passively or actively, across the alveoli epithelium and capillary epithelium layers into the bloodstream for subsequent systemic distribution.

Pulmonary administration of a polypeptide or protein such as IFN-β requires dispensing of the biologically active substance from a delivery device into a subject's oral cavity during inhalation. For purposes of the present invention, HSA-free pharmaceutical compositions comprising IFN-β or variants thereof are administered via inhalation of an aerosol or other suitable preparation that is obtained from an aqueous or nonaqueous solution or suspension form, or a solid or dry powder form of the pharmaceutical composition, depending upon the delivery device used. Such delivery devices are well known in the art and include, but are not limited to, nebulizers, metered-dose inhalers, and dry powder inhalers, or any other appropriate delivery mechanisms

-9-

that allow for dispensing of a pharmaceutical composition as an aqueous or nonaqueous solution or suspension or as a solid or dry powder form. When used in the context of pharmaceutical compositions suitable for pulmonary delivery, these terms have the following intended meaning. By "aqueous" is intended a composition prepared with, containing, or dissolved in water, including mixtures wherein water is the predominating substance in the mixture. A predominating substance is present in a greater quantity than another component of the mixture. By "nonaqueous" is intended a composition prepared with, containing, or dissolved in a substance other than water or mixtures wherein water is not the predominating substance in the mixture. By "solution" is intended a homogeneous preparation of two or more substances, which may be solids, liquids, gases, or intercombinations thereof. By "suspension" is intended a mixture of substances such that one or more insoluble substances are homogeneously dispersed in another predominating substance.

For purposes of the present invention, the terms "solid" and "dry powder" are used interchangeably with reference to the HSA-free pharmaceutical compositions suitable for pulmonary delivery. By "solid" or "dry powder" form of a pharmaceutical composition is intended the composition has been dried to a finely divided powder having a moisture content below about 10% by weight, usually below about 5% by weight, and preferably below about 3% by weight. This dry powder form of the composition consists of particles comprising the IFN-β or variants thereof. Preferred particle sizes are less than about 10.0 μm mean diameter, more preferably less than about 7.0 μm, even more preferably about less than about 6.0 μm, even more preferably in the range of 0.1 to 5.0 μm, most preferably in the range of about 1.0 to about 5.0 μm mean diameter.

Thus, an HSA-free liquid pharmaceutical composition comprising IFN-β or variants thereof which is intended for pulmonary delivery can either be used as a liquid solution or suspension in the delivery device or first be processed into a dry powder form using lyophilization or spray-drying techniques well known in the art. Where a liquid solution or suspension is used in the delivery device, a nebulizer, a metered dose inhaler, or other suitable delivery device delivers, in a single or multiple fractional dose, by

-10-

pulmonary inhalation a pharmaceutically effective amount of the composition to the subject's lungs as droplets having the same particle size range noted above for the dry powder form. By "pharmaceutically effective amount" is intended an amount that is useful in the treatment, prevention, or diagnosis of a disease or condition responsive to

5 IFN-β. The liquid solution or suspension of the composition may be used with physiologically appropriate stabilizing agents, excipients, viscosity modifiers, bulking agents, surfactants, or combinations thereof, known to those of skill in the art, so long as they don't compromise the distinguishing characteristics of the HSA-free IFN-β compositions of the invention.

10 Where the liquid pharmaceutical composition is lyophilized prior to use in pulmonary delivery, the lyophilized composition is milled to obtain the finely divided dry powder consisting of particles within the desired size range noted above. Where spray-drying is used to obtain a dry powder form of the liquid pharmaceutical composition, the process is carried out under conditions that result in a substantially amorphous finely

15 divided dry powder consisting of particles within the desired size range noted above. Similarly, if the starting pharmaceutical composition is already in a lyophilized form, the composition can be milled to obtain the dry powder form for subsequent preparation as an aerosol or other preparation suitable for pulmonary inhalation. Where the starting pharmaceutical composition is in its spray-dried form, the composition has preferably

20 been prepared such that it is already in a dry powder form having the appropriate particle size for dispensing as an aqueous or nonaqueous solution or suspension or dry powder form in accordance pulmonary administration. For methods of preparing dry powder forms of pharmaceutical compositions, see, for example, WO 96/32149, WO 97/41833, WO 98/29096, and U.S. Patent Nos. 5,976,574, 5,985,248, and 6,001,336; herein

25 incorporated by reference.

The resulting dry powder form of the composition is then placed within an appropriate delivery device for subsequent preparation as an aerosol or other suitable preparation that is delivered to the subject via pulmonary inhalation. Where the dry powder form of the pharmaceutical composition is to be prepared and dispensed as an

30 aqueous or nonaqueous solution or suspension, a metered-dose inhaler, or other

-11-

appropriate delivery device is used. A pharmaceutically effective amount of the dry powder form of the composition is administered in an aerosol or other preparation suitable for pulmonary inhalation. The amount of dry powder form of the composition placed within the delivery device is sufficient to allow for delivery of a pharmaceutically

5 effective amount of the composition to the subject by inhalation. Thus, the amount of dry powder form to be placed in the delivery device will compensate for possible losses to the device during storage and delivery of the dry powder form of the composition. Following placement of the dry powder form within a delivery device, the properly sized particles as noted above are suspended in an aerosol propellant. The pressurized

10 nonaqueous suspension is then released from the delivery device into the air passage of the subject while inhaling. The delivery device delivers, in a single or multiple fractional dose, by pulmonary inhalation a pharmaceutically effective amount of the composition to the subject's lungs. The aerosol propellant may be any conventional material employed for this purpose, such as a chlorofluorocarbon, a hydrochloro-fluorocarbon, a

15 hydrofluorocarbon, or a hydrocarbon, including trichlorofluoromethane, dichlorodifluoro-methane, dichlorotetrafluoromethane, dichlorodifluoro-methane, dichlorotetrafluoroethanol, and 1,1,1,2-tetra-fluoroethane, or combinations thereof. A surfactant may be added to the pharmaceutical composition to reduce adhesion of the protein-containing dry powder to the walls of the delivery device from which the aerosol

20 is dispensed. Suitable surfactants for this intended use include, but are not limited to, sorbitan trioleate, soya lecithin, and oleic acid. Devices suitable for pulmonary delivery of a dry powder form of a protein composition as a nonaqueous suspension are commercially available. Examples of such devices include the Ventolin metered-dose inhaler (Glaxo Inc., Research Triangle Park, NC) and the Intal Inhaler (Fisons, Corp.,

25 Bedford, MA). See also the aerosol delivery devices described in U.S. Patent Nos. 5,522,378, 5,775,320, 5,934,272 and 5,960,792, herein incorporated by reference.

Where the solid or dry powder form of the HSA-free IFN-ß pharmaceutical composition is to be delivered as a dry powder form, a dry powder inhaler or other appropriate delivery device is preferably used. The dry powder form of the

30 pharmaceutical composition is preferably prepared as a dry powder aerosol by dispersion

-12-

in a flowing air or other physiologically acceptable gas stream in a conventional manner. Examples of commercially available dry powder inhalers suitable for use in accordance with the methods herein include the Spinhaler powder inhaler (Fisons Corp., Bedford, MA) and the Ventolin Rotahaler (Glaxo, Inc., Research Triangle Park, NC). See also the

5   dry powder delivery devices described in WO 93/00951, WO 96/09085, WO 96/32152, and U.S. Patent Nos. 5,458,135, 5,785,049, and 5,993,783, herein incorporated by reference.

The dry powder form of the HSA-free pharmaceutical composition comprising IFN-β or biologically active variant thereof can be reconstituted to an aqueous solution

10   for subsequent delivery as an aqueous solution aerosol using a nebulizer, a metered dose inhaler, or other suitable delivery device. In the case of a nebulizer, the aqueous solution held within a fluid reservoir is converted into an aqueous spray, only a small portion of which leaves the nebulizer for delivery to the subject at any given time. The remaining spray drains back into a fluid reservoir within the nebulizer, where it is aerosolized again

15   into an aqueous spray. This process is repeated until the fluid reservoir is completely dispensed or until administration of the aerosolized spray is terminated. Such nebulizers are commercially available and include, for example, the Ultravent nebulizer (Mallinckrodt Inc., St. Louis, MO) and the Acorn II nebulizer (Marquest Medical Products, Englewood, CO). See also the nebulizer described in WO 93/00951, and the

20   device for delivering aerosolized aqueous formulations described in U.S. Patent No. 5,544,646; herein incorporated by reference.

The HSA-free IFN-β pharmaceutical compositions of the present invention-are "stabilized" compositions. By "stabilized" is intended the compositions retain the IFN-β polypeptide in its substantially monomeric state during storage, and hence the therapeutic

25   effectiveness of this polypeptide is not compromised due to aggregate formation. By "during storage" is intended a liquid pharmaceutical composition or formulation once prepared, is not immediately administered to a subject. Rather, following preparation, it is packaged for storage, either in a liquid form, in a frozen state, or in a dried form for later reconstitution into a liquid form or other form suitable for administration to a subject.

30   This stability is achieved in the absence of the use of HSA as a stabilizing and

-13-

solubilizing agent. Preferably, compositions of the invention are stored directly in their liquid form to take full advantage of the convenience of having storage stability in the liquid form, ease of administration without reconstitution, and ability to supply the formulation in prefilled, ready-to-use syringes or as multidose preparations if the

5   formulation is compatible with bacteriostatic agents. The stabilized HSA-free IFN-β compositions of the invention preferably have a shelf-life of at least about 6 months, 12 months, 18 months, more preferably at least 20 months, still more preferably at least about 22 months, most preferably at least about 24 months when stored at 2-8°C.

Methods for monitoring stability of the HSA-free IFN-β pharmaceutical

10   compositions of the invention are available in the art, including those methods described in the examples disclosed herein. Thus, IFN-β aggregate formation during storage of a liquid pharmaceutical composition of the invention can be readily determined by measuring the change in soluble IFN-β in solution over time. Amount of soluble polypeptide in solution can be quantified by a number of analytical assays adapted to

15   detection of IFN-β. Such assays include, for example, reverse phase (RP)-HPLC and UV absorption spectroscopy, as described in the Examples below. Determination of both soluble and insoluble aggregates during storage in liquid formulations can be achieved, for example, using analytical ultracentrifugation as noted in the Examples below to distinguish between that portion of the soluble polypeptide that is present as soluble

20   aggregates and that portion that is present in the nonaggregate, biologically active molecular form.

The stabilized pharmaceutical formulations of the invention comprise IFN-β and variants thereof. The term "IFN-β" as used herein refers to IFN-β or variants thereof, sometimes referred to as IFN-β-like polypeptides. Human IFN-β variants, which may be

25   naturally occurring (e.g., allelic variants that occur at the IFN-β locus) or recombinantly produced, have amino acid sequences that are the same as, similar to, or substantially similar to the mature native IFN-β sequence. Fragments of IFN-β or truncated forms of IFN-β that retain their activity are also encompassed. These biologically active fragments or truncated forms of IFN-β are generated by removing amino acid residues

-14-

from the full-length IFN-β amino acid sequence using recombinant DNA techniques well known in the art. IFN-β polypeptides may be glycosylated or unglycosylated, as it has been reported in the literature that both the glycosylated and unglycosylated IFN-β's show qualitatively similar specific activities and that, therefore, the glycosyl moieties are

5   not involved in and do not contribute to the biological activity of IFN-β.

The IFN-β variants encompassed herein include muteins of the mature native IFN-β sequence, wherein one or more cysteine residues that are not essential to biological activity have been deliberately deleted or replaced with other amino acids to eliminate sites for either intermolecular crosslinking or incorrect intramolecular disulfide bond

10   formation. IFN-β variants of this type include those containing a glycine, valine, alanine, leucine, isoleucine, tyrosine, phenylalanine, histidine, tryptophan, serine, threonine, or methionine substituted for the cysteine found at amino acid 17 of the mature native amino acid sequence. Serine and threonine are the more preferred replacements because of their chemical analogy to cysteine. Serine substitutions are most preferred. In one

15   embodiment, the cysteine found at amino acid 17 of the mature native sequence is replaced with serine. Cysteine 17 may also be deleted using methods known in the art (see, for example, U.S. Patent No. 4,588,584, herein incorporated by reference), resulting in a mature IFN-β mutein that is one amino acid shorter than the mature native IFN-β. See also, as examples, U.S. Patent Nos. 4,530,787; 4,572,798; and 4,588,585. Thus, IFN-

20   β variants with one or more mutations that improve, for example, their pharmaceutical utility are also encompassed by the present invention.

The skilled artisan will appreciate that additional changes can be introduced by mutation into the nucleotide sequences encoding IFN-β, thereby leading to changes in the IFN-β amino acid sequence, without altering the biological activity of the interferon.

25   Thus, an isolated nucleic acid molecule encoding an IFN-β variant having a sequence that differs from the amino acid sequence for the mature native IFN-β can be created by introducing one or more nucleotide substitutions, additions, or deletions into the corresponding nucleotide sequence disclosed herein, such that one or more amino acid substitutions, additions or deletions are introduced into the encoded IFN-β. Mutations

-15-

can be introduced by standard techniques, such as site-directed mutagenesis and PCR-mediated mutagenesis. Such IFN-β variants are also encompassed by the present invention.

For example, conservative amino acid substitutions may be made at one or more

5 predicted, preferably nonessential amino acid residues. A "nonessential" amino acid residue is a residue that can be altered from the wild-type sequence of IFN-β without altering its biological activity, whereas an "essential" amino acid residue is required for biological activity. A "conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families

10 of amino acid residues having similar side chains have been defined in the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan),

15 beta-branched side chains (e.g., threonine, valine, isoleucine), and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Such substitutions would not be made for conserved amino acid residues, or for amino acid residues residing within a conserved motif.

Alternatively, variant IFN-β nucleotide sequences can be made by introducing

20 mutations randomly along all or part of an IFN-β coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for IFN-β biological activity to identify mutants that retain activity. Following mutagenesis, the encoded protein can be expressed recombinantly, and the activity of the protein can be determined using standard assay techniques described herein.

25 Biologically active variants of IFN-β will generally have at least 80%, more preferably about 90% to about 95% or more, and most preferably about 96% to about 99% or more amino acid sequence identity to the amino acid sequence of mature native IFN-β, which serves as the basis for comparison. By "sequence identity" is intended the same amino acid residues are found within the variant polypeptide and the polypeptide

-16-

molecule that serves as a reference when a specified, contiguous segment of the amino acid sequence of the variant is aligned and compared to the amino acid sequence of the reference molecule.

For purposes of optimal alignment of the two sequences for the purposes of sequence identity determination, the contiguous segment of the amino acid sequence of the variant may have additional amino acid residues or deleted amino acid residues with respect to the amino acid sequence of the reference molecule. The contiguous segment used for comparison to the reference amino acid sequence will comprise at least 20 contiguous amino acid residues. Corrections for increased sequence identity associated with inclusion of gaps in the variant's amino acid sequence can be made by assigning gap penalties. Methods of sequence alignment are well known in the art.

Thus, the determination of percent identity between any two sequences can be accomplished using a mathematical algorithm. One preferred, non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the algorithm of Myers and Miller (1988) *Comput. Appl. Biosci.* 4:11-7. Such an algorithm is utilized in the ALIGN program (version 2.0), which is part of the GCG alignment software package. A PAM120 weight residue table, a gap length penalty of 12, and a gap penalty of 4 can be used with the ALIGN program when comparing amino acid sequences. Another preferred, non-limiting example of a mathematical algorithm for use in comparing two sequences is the algorithm of Karlin and Altschul (1990) *Proc. Natl. Acad. Sci. USA* 90:5873-5877, modified as in Karlin and Altschul (1993) *Proc. Natl. Acad. Sci USA* 90:5873-5877. Such an algorithm is incorporated into the NBLAST and XBLAST programs of Altschul *et al.* (1990) *J. Mol. Biol.* 215:403-410. BLAST amino acid sequence searches can be performed with the XBLAST program, score = 50, wordlength = 3, to obtain amino acid sequence similar to the polypeptide of interest. To obtain gapped alignments for comparison purposes, gapped BLAST can be utilized as described in Altschul *et al.* (1997) *Nucleic Acids Res.* 25:3389-3402. Alternatively, PSI-BLAST can be used to perform an integrated search that detects distant relationships between molecules. See Altschul *et al.* (1997) *supra.* When utilizing BLAST, gapped BLAST, or PSI-BLAST programs, the default parameters can be used. *See*

-17-

http://www.ncbi.nlm.nih.gov. Also see the ALIGN program (Dayhoff (1978) in *Atlas of Protein Sequence and Structure* 5:Suppl. 3, National Biomedical Research Foundation, Washington, D.C.) and programs in the Wisconsin Sequence Analysis Package, Version 8 (available from Genetics Computer Group, Madison, Wisconsin), for example, the

5   GAP program, where default parameters of the programs are utilized.

When considering percentage of amino acid sequence identity, some amino acid residue positions may differ as a result of conservative amino acid substitutions, which do not affect properties of protein function. In these instances, percent sequence identity may be adjusted upwards to account for the similarity in conservatively substituted amino

10   acids. Such adjustments are well known in the art. See, for example, Myers and Miller (1988) *Comput. Appl. Biosci.* 4:11-17.

Biologically active IFN-β variants encompassed by the invention also include IFN-β polypeptides that have been covalently linked with, for example, polyethylene glycol (PEG) or albumin. These covalent hybrid IFN-β molecules possess certain

15   desirable pharmaceutical properties such as an extended serum half-life after administration to a patient. Methods for creating PEG-IFN adducts involve chemical modification of monomethoxypolethylene glycol to create an activated compound that will react with IFN-β. Methods for making and using PEG-linked polypeptides are described, for example in Delgado *et al.* (1992) *Crit. Rev. Ther. Drug. Carrier Syst.*

20   9:249-304. Methods for creating albumin fusion polypeptides involve fusion of the coding sequences for the polypeptide of interest (*e.g.*, IFN-β) and albumin and are described in U.S. Patent No. 5,876,969, herein incorporated by reference.

Biologically active variants of IFN-β encompassed by the invention should retain IFN-β activities, particularly the ability to bind to IFN-β receptors. In some

25   embodiments, the IFN-β variant retains at least about 25%, about 50%, about 75%, about 85%, about 90%, about 95%, about 98%, about 99% or more of the biologically activity of the polypeptides whose amino acid sequences are given in Figure 1 or 2. IFN-β variants whose activity is increased in comparison with the activity of the polypeptides shown in Figure 1 or 2 are also encompassed. The biological activity of IFN-β variants

can be measured by any method known in the art. Examples of such assays can be found in Fellous *et al.* (1982) *Proc. Natl. Acad. Sci USA* 79:3082-3086; Czerniecki *et al.* (1984) *J. Virol.* 49(2):490-496; Mark *et al.* (1984) *Proc. Natl Acad. Sci. USA* 81:5662-5666; Branca *et al.* (1981) *Nature* 277:221-223; Williams *et al.* (1979) *Nature* 282:582-586;

5   Herberman *et al.* (1979) *Nature* 277:221-223; Anderson *et al.* (1982) *J. Biol. Chem.* 257(19):11301-11304; and the IFN-β potency assay described herein (see Example 2).

The IFN-β of the formulations of the invention can be from any animal species including, but not limited to, avian, canine, bovine, porcine, equine, and human. Preferably, the IFN-β is from a mammalian species when the formulation is to be used in

10   treatment of a mammalian IFN-β disorder, and more preferably is from a mammal of the same species as the mammal undergoing treatment for such a disorder. Thus, where the mammal undergoing treatment is a human, preferably the subject is administered an HSA-free pharmaceutical composition comprising substantially monomeric human IFN-β or biologically active variant thereof.

15   Non-limiting examples of IFN-β polypeptides and IFN-β variant polypeptides encompassed by the invention are set forth in Nagata *et al.* (1980) *Nature* 284:316-320; Goeddel *et al.* (1980) *Nature* 287:411-416; Yelverton *et al.* (1981) *Nucleic Acids Res.* 9:731-741; Streuli *et al.* (1981) *Proc. Natl. Acad. Sci. U.S.A.* 78:2848-2852; EP028033B1, and EP109748B1. See also U.S. Patent Nos. 4,518,584; 4,569,908;

20   4,588,585; 4,738,844; 4,753,795; 4,769,233; 4,793,995; 4,914,033; 4,959,314; 5,545,723; and 5,814,485. These disclosures are herein incorporated by reference. These citations also provide guidance regarding residues and regions of the IFN-β polypeptide that can be altered without the loss of biological activity.

In one embodiment of the present invention, the IFN-β within the stabilized

25   pharmaceutical formulations is the mature native IFN-β polypeptide. In another embodiment, the IFN-β in these formulations is the mature IFN-β polypeptide wherein the cysteine found at amino acid 17 of the mature native sequence is replaced with serine as discussed above. However, the present invention encompasses other embodiments

where the IFN-β within the stabilized pharmaceutical formulation is any biologically active IFN-β polypeptide or variant as described elsewhere herein.

In some embodiments of the present invention, the IFN-β is recombinantly produced. By "recombinantly produced IFN-β" is intended IFN-β that has comparable biological activity to mature native IFN-β and that has been prepared by recombinant DNA techniques. IFN-β can be produced by culturing a host cell transformed with an expression vector comprising a nucleotide sequence that encodes an IFN-β polypeptide. The host cell is one that can transcribe the nucleotide sequence and produce the desired protein, and can be prokaryotic (for example, *E. coli*) or eukaryotic (for example a yeast, insect, or mammalian cell). Examples of recombinant production of IFN-β are given in Mantei *et al.* (1982) *Nature* 297:128; Ohno *et al.* (1982) *Nucleic Acids Res.* 10:967; Smith *et al.* (1983) *Mol. Cell. Biol.* 3:2156, and U.S. Patent No.4,462,940, 5,702,699, and 5,814,485; herein incorporated by reference. Human interferon genes have been cloned using recombinant DNA ("rDNA") technology and have been expressed in *E. coli* (Nagola *et al.* (1980) *Nature* 284:316; Goeddel *et al.* (1980) *Nature* 287:411; Yelverton *et al.* (1981) *Nuc. Acid Res.* 9:731; Streuli *et al.* (1981) *Proc. Natl. Acad. Sci. U.S.A.* 78:2848). Alternatively, IFN-β can be produced by a transgenic animal or plant that has been genetically engineered to express the IFN-β protein of interest in accordance with methods known in the art.

Proteins or polypeptides that exhibit native interferon-beta-like properties may also be produced with rDNA technology by extracting poly-A-rich 12S messenger RNA from virally induced human cells, synthesizing double-stranded cDNA using the mRNA as a template, introducing the cDNA into an appropriate cloning vector, transforming suitable microorganisms with the vector, harvesting the microorganisms, and extracting the interferon-beta therefrom. See, for example, European Patent Application Nos. 28033 (published May 6, 1981); 32134 (published July 15, 1981); and 34307 (published August 26, 1981), which describe various methods for the production of interferon-beta employing rDNA techniques.

Alternatively, IFN-β can be synthesized chemically, by any of several techniques that are known to those skilled in the peptide art. See, for example, Li *et al.* (1983*) Proc. Natl. Acad. Sci. USA* 80:2216-2220, Steward and Young (1984) *Solid Phase Peptide Synthesis* (Pierce Chemical Company, Rockford, Illinois), and Baraney and Merrifield

5   (1980) *The Peptides: Analysis, Synthesis, Biology*, ed. Gross and Meinhofer, Vol. 2 (Academic Press, New York, 1980), pp. 3-254, discussing solid-phase peptide synthesis techniques; and Bodansky (1984) *Principles of Peptide Synthesis* (Springer-Verlag, Berlin) and Gross and Meinhofer, eds. (1980) *The Peptides: Analysis, Synthesis, Biology*, Vol. 1 (Academic Press, New York), discussing classical solution synthesis. IFN-β can

10   also be chemically prepared by the method of simultaneous multiple peptide synthesis. See, for example, Houghten (1984) *Proc. Natl. Acad. Sci. USA* 82:5131-5135; and U.S. Patent No. 4,631,211.

The recombinantly produced IFN-β for use in preparing the stabilized HSA-free IFN-β pharmaceutical compositions of the invention can be recovered and purified using

15   any method known to one of skill in the art. Such methods include those disclosed in U.S. Patent Nos. 4,462,940 and 5,702,699, herein incorporated by reference. These methods recover the interferon in a pure form of IFN-β that tends to form aggregates in the absence of SDS, which is used as a solubilizing agent. Further, these methods expose the protein to high pH conditions that may adversely affect the protein's biological

20   properties, and can result in compositions containing residual amounts of SDS used to solubilize the protein during purification. Thus, while the IFN-β may be obtained using these methods, preferably it is recovered and purified by the improved method disclosed in the copending provisional application entitled *"Improved Method of Protein Purification and Recovery,"* filed October 27, 2000, and assigned U.S. Application Serial

25   No. 60/243,965, copending provisional application entitled *"Improved Method of Protein Purification and Recovery,"* filed April 9, 2001, and assigned U.S. Application Serial No. 60/282,607, and the provisional application filed concurrently herewith entitled *"Methods of Protein Purification and Recovery,"* and assigned U.S. Application Serial No. _____; the contents of which are herein incorporated by reference in their entirety.

Two improved purification and recovery methods for IFN-β are disclosed in these copending and concurrently filed applications. The first of these purification and recovery methods comprises precipitating substantially purified IFN-β with an alcohol such as an aliphatic alcohol, and dissolving the precipitated IFN-β into guanidine

5   hydrochloride. The resulting solution is then diluted into an appropriate buffer to renature the protein. The second of these purification and recovery methods omits the precipitation step. In this manner, a sample comprising substantially purified IFN-β is mixed with guanidine hydrochloride to form a solution comprising solubilized denatured IFN-β; this solution is then diluted into an appropriate buffer to renature the protein. In

10   both methods, the solution comprising renatured IFN-β is then diafiltered or dialyzed into a buffer used for pharmaceutical purposes. When used to prepare an HSA-free pharmaceutical composition of the present invention, the purified renatured IFN-β protein is diafiltered or dialyzed into a low-ionic-strength formulation of the present invention as described in Example 8 below.

15   Compositions encompassed by the invention may have as little as about 0.01 mg/ml IFN-β and as much as about 20.0 mg/ml IFN-β (weight/volume). In various embodiments, the IFN-β is present at a concentration of about 0.01 mg/ml to about 20.0 mg/ml, about 0.015 mg/ml to about 12.5 mg/ml, about 0.025 mg/ml to about 10.0 mg/ml, about 0.05 mg/ml to about 8.0 mg/ml, about 0.075 mg/ml to about 6.0 mg/ml, about 0.1

20   mg/ml to about 4.0 mg/ml, about 0.125 mg/ml to about 2.0 mg/ml, about 0.175 mg/ml to about 1.0 mg/ml, about 0.2 mg/ml to about 0.5 mg/ml, about 0.225 mg/ml to about 0.3 mg/ml, and about 0.25 mg/ml.

In some embodiments, the formulations of the invention comprise a pharmaceutically acceptable carrier. By "pharmaceutically acceptable carrier" is

25   intended a carrier that is conventionally used in the art to facilitate the storage, administration, and/or the healing effect of the therapeutic ingredients. A carrier may also reduce any undesirable side effects of the IFN-β. A suitable carrier should be stable, i.e., incapable of reacting with other ingredients in the formulation. It should not produce significant local or systemic adverse effects in recipients at the dosages and

30   concentrations employed for treatment. Such carriers are generally known in the art.

-22-

Suitable carriers for this invention are those conventionally used large stable macromolecules such as gelatin, collagen, polysaccharide, monosaccharides, polyvinyl-pyrrolidone, polylactic acid, polyglycolic acid, polymeric amino acids, fixed oils, ethyl oleate, liposomes, glucose, lactose, mannose, dextrose, dextran, cellulose, sorbitol,

5   polyethylene glycol (PEG), and the like. Slow-release carriers, such as hyaluronic acid, may also be suitable. See particularly Prisell *et al.* (1992) *Int. J. Pharmaceu.* 85:51-56, and U.S. Patent No. 5,166,331.

The pharmaceutical composition may additionally comprise a solubilizing agent or solubility enhancer that contributes to the protein's solubility beyond the enhanced

10   solubility obtained using the low-ionic-strength formulations disclosed herein. Compounds containing a guanidinium group, most preferably arginine, are suitable solubility enhancers for IFN-β. Examples of such solubility enhancers include the amino acid arginine, as well as amino acid analogues of arginine that retain the ability to enhance solubility of IFN-β. Such analogues include, without limitation, dipeptides and

15   tripeptides that contain arginine. Additional suitable solubilizing agents are discussed in U.S. Paten Nos. 4,816,440; 4,894,330; 5,004,605; 5,183,746; 5,643,566; and in Wang *et al.* (1980) *J. Parenteral Drug Assoc.* 34:452-462; herein incorporated by reference.

In addition to those agents disclosed above, other stabilizing agents, such as ethylenediaminetetracetic acid (EDTA) or one of its salts such as disodium EDTA, can be

20   added to further enhance the stability of the liquid pharmaceutical compositions. The EDTA acts as a scavenger of metal ions known to catalyze many oxidation reactions, thus providing an additional stabilizing agent. Other suitable stabilizing agents include non-ionic surfactants, including polyoxyethylene sorbitol esters such as polysorbate 80 (Tween 80) and polysorbate 20 (Tween 20); polyoxypropylene-polyoxyethylene esters

25   such as Pluronic F68 and Pluronic F127; polyoxyethylene alcohols such as Brij 35; simethicone; polyethylene glycol such as PEG400; lysophosphatidylcholine; and polyoxyethylene-p-t-octylphenol such as Triton X-100. Classic stabilization of pharmaceuticals by surfactants is described, for example, in Levine et al.(1991) *J. Parenteral Sci. Technol.* 45(3):160-165, herein incorporated by reference.

-23-

A pharmaceutically effective amount of a stabilized liquid HSA-free IFN-β formulation or the invention, or of a reconstituted stabilized lyophilized HSA-free IFN-β pharmaceutical formulation of the invention is administered to a subject. By "pharmaceutically effective amount" is intended an amount that is useful in the treatment,

5   prevention, or diagnosis of a disease or condition. Typical routes of administration include, but are not limited to, oral administration, nasal delivery, pulmonary delivery, and parenteral administration, including transdermal, intravenous, intramuscular, subcutaneous, intraarterial, and intraperitoneal injection or infusion. In one such embodiment, the administration is by injection, preferably subcutaneous injection.

10   Injectable forms of the compositions of the invention include, but are not limited to, solutions, suspensions, and emulsions. Typically, a therapeutically effective amount of IFN-β comprises about 0.01 μg/kg to about 5 mg/kg of the composition, preferably about 0.05 μg/kg to about 1000 μg/kg, more preferably about 0.1 μg/kg to about 500 μg/kg, even more preferably still about 0.5 μg/kg to about 30 μg/kg.

15   In one embodiment, the stabilized HSA-free pharmaceutical composition comprising substantially monomeric IFN-β is formulated in a unit dosage and may be in an injectable or infusible form such as solution, suspension, or emulsion. Furthermore, it can be stored frozen or prepared in the dried form, such as lyophilized powder, which can be reconstituted into the liquid solution, suspension, or emulsion before administration by

20   any of various methods including oral or parenteral routes of administration. The stabilized pharmaceutical composition may be sterilized by membrane filtration and is stored in unit-dose or multi-dose containers such as sealed vials or ampules. Additional methods for formulating a pharmaceutical composition generally known in the art may be used to further enhance storage stability of the pharmaceutical compositions disclosed

25   herein provided they do not adversely affect the beneficial effects of the stabilizing agents as disclosed herein. A thorough discussion of formulation and selection of pharmaceutically acceptable carriers, stabilizers, etc. can be found in *Remington's Pharmaceutical Sciences* (1990) (18th ed., Mack Publishing Company, Eaton, Pennsylvania), herein incorporated by reference.

-24-

Formulations comprising an effective amount of the pharmaceutical compositions of the invention comprising β-interferon (IFN-β) or variant thereof, such as the mutein of human IFN-β (hIFN-β) designated hIFN-β_{ser17}, are useful in the diagnosis, prevention, and treatment (local or systemic) of clinical indications responsive to therapy with this

5   polypeptide. Such clinical indications include, for example, disorders or diseases of the central nervous system (CNS), brain, and/or spinal cord, including Alzheimer's disease, Parkinson's disease, Lewy body dementia, multiple sclerosis, epilepsy, cerebellar ataxia, progressive supranuclear palsy, amyotrophic lateral sclerosis, affective disorders, anxiety disorders, obsessive compulsive disorders, personality disorders, attention deficit

10   disorder, attention deficit hyperactivity disorder, Tourette Syndrome, Tay Sachs, Nieman Pick, and schizophrenia; nerve damage from cerebrovascular disorders such as stroke in the brain or spinal cord, from CNS infections including meningitis and HIV, from tumors of the brain and spinal cord, or from a prion disease; autoimmune diseases, including acquired immune deficiency, rheumatoid arthritis, psoriasis, Crohn's disease, Sjogren's

15   syndrome, amyotropic lateral sclerosis, and lupus; and cancers, including breast, prostate, bladder, kidney and colon cancers. Administration of IFN-β or its muteins to humans or animals may be delivered orally, intraperitoneally, intramuscularly, subcutaneously, intravenously, intranasally, or by pulmonary delivery as deemed appropriate by the physician.

20   The present invention provides a method for increasing solubility of interferon-beta (IFN-β) or biologically active variant thereof in a pharmaceutical composition in the absence of human serum albumin. The method comprises preparing the composition with a low-ionic-strength formulation as disclosed elsewhere herein such that the pH of the composition is maintained at about pH 3.0 to about pH 5.0, and incorporating the

25   IFN-β or biologically active variant thereof into the composition. In one embodiment, the low-ionic-strength formulation comprises glycine, aspartic acid, or sodium succinate as the buffer at a concentration of about 1 mM to about 30 mM, preferably about 2 mM to about 5 mM. The composition may further comprise a non-ionic tonicifying agent in an amount sufficient to render the composition isotonic with body fluids as disclosed

30   elsewhere herein. In one embodiment, the non-ionic tonicifying agent is selected from

-25-

the group consisting of trehalose, sucrose, mannitol, and any combination thereof. Further, by maintaining the pH of this composition between about pH 3.0 and pH 5.0, preferably pH 4.0, it is possible to retain the majority of the IFN-β in its monomeric state. Thus the invention also provides a method for preparing a stabilized HSA-free

5   pharmaceutical composition comprising substantially monomeric IFN-β.

The following examples are offered by way of illustration and not by way of limitation.

EXPERIMENTAL

10   The current invention was made by better understanding the solubility and stability properties of IFN-β-1b. The preferred characteristics of the HSA free IFN-β-1b formulations are a pH range of about pH 3.0 to about pH 5.0 and very low-ionic-strength conditions. The use of very low-ionic-strength conditions within this pH range results in a higher content of monomeric IFN-β-1b and lower content of aggregated IFN-β-1b

15   species. These conditions provide for IFN-β-1b solubility and stability not previously attainable without the use of HSA in the formulation. They also provide for formulations having the maximum content of monomeric IFN-β-1b.

IFN-β-1b for use in these experiments was produced in *E. coli* essentially as described in the first several steps of purification set forth in U.S. Patent Nos. 4,462,940

20   and/or 4,816,400. That is, transformed bacteria were used to produce IFN-β; the host cells were concentrated, and their cell walls disrupted to obtain IFN-β-1b bulk material.

The IFN-β-1b bulk material so obtained contains 50 mM sodium acetate, 1 mM EDTA, 0.1% sodium dodecyl sulfate (SDS) at pH 5.5. To create the starting material for solubility and stability measurements described below, SDS was removed from the IFN-

25   β-1b bulk material by processing the material through a G-25 column (Pharmacia) equilibrated with 1.5 mM sodium hydroxide at >pH 11. After collecting the pool from the G-25 column, a volume of 1 M glycine, pH 3, equal to approximately 1/10 of the pool was added with rapid stirring to adjust the pool to ~pH 3. Materials were stored at 4°C or frozen for subsequent use in solubility and stability measurements.

30

Example 1: - Determining the Solubility of IFN-β-1b

Initial experiments were conducted to understand the solubility of IFN-β-1b under a wide variety of conditions of pH, buffer type, and ionic strength. A solution of IFN-β-1b (~0.8 mg/ml IFN-β-1b in 100 mM glycine, pH 3.0) was dialyzed against the buffers in Table 1. Results are shown in Figure 1. These results show that the solubility of IFN-β-1b is dependent upon pH and ionic strength. The IFN-β-1b at pH 3.0 remains soluble at all concentrations of sodium chloride to 200 mM. For formulations at pH 4.0, the IFN-β-1b becomes less soluble as the sodium chloride concentration reaches 150 mM. For formulations at pH 5.0, IFN-β-1b becomes less soluble when the formulation contains only 100 mM sodium chloride. Taken together, these data indicate that IFN-β-1b is most soluble in formulations at pH 3.0, less soluble in formulations at pH 4.0, and least soluble at pH 5.0. These data also indicate that increasing the ionic strength of formulations (by increasing the sodium chloride concentration) also decreases the solubility of IFN-β-1b.

While the above experiment was able to determine conditions favorable for IFN-β-1b solubility, it did not determine the solubility limit at any of the given conditions. A subsequent experiment was conducted to determine the solubility limits of IFN-β-1b. To maximize IFN-β-1b, low-ionic-strength formulations were used (i.e., 5 mM buffer and no salts such as sodium chloride). After dialysis, IFN-β-1b was concentrated to determine the solubility limit in a given formulation. Results of these experiments are shown in Figure 2. Formulations at pH 3.0 and 4.0 are most soluble, showing a solubility of at least 16 mg/ml. The formulation at pH 5 was soluble to approximately 8 mg/ml. Formulations above pH 5.0 were soluble only to approximately 0.2 mg/ml. These results again indicate that pH has a powerful effect on IFN-β-1b solubility. Low-ionic-strength formulations at pH 3.0 and pH 4.0 are more soluble than at pH 5.0. Above pH 5.0, IFN-β-1b is essentially insoluble in low-ionic-strength formulations.

Table 1: Formulations to Examine IFN-β-1b Solubility pH, Buffer Type and Sodium Chloride Concentration

Buffer	pH	Sodium Chloride Concentration (mM)
5 mM Glycine	pH 3	0 mM
5 mM Glycine	pH 3	50 mM
5 mM Glycine	pH 3	100 mM
5 mM Glycine	pH 3	150 mM
5 mM Citrate	pH 4	0 mM
5 mM Citrate	pH 4	50 mM
5 mM Citrate	pH 4	100 mM
5 mM Citrate	pH 4	150 mM
5 mM Acetate	pH 4	0 mM
5 mM Acetate	pH 4	50 mM
5 mM Acetate	pH 4	100 mM
5 mM Acetate	pH 4	150 mM
5 mM Formate	pH 4	0 mM
5 mM Formate	pH 4	50 mM
5 mM Formate	pH 4	100 mM
5 mM Formate	pH 4	150 mM
5 mM Acetate	pH 5	0 mM
5 mM Acetate	pH 5	50 mM
5 mM Acetate	pH 5	100 mM
5 mM Acetate	pH 5	150 mM
5 mM Histidine	pH 5	0 mM
5 mM Histidine	pH 5	50 mM
5 mM Histidine	pH 5	100 mM
5 mM Histidine	pH 5	150 mM
5 mM Sodium succinate	pH 5	0 mM
5 mM Sodium succinate	pH 5	50 mM
5 mM Sodium succinate	pH 5	100 mM
5 mM Sodium succinate	pH 5	150 mM

Example 2 - Analytical Ultracentrifugation Experiments

While solubility experiments can determine how much IFN-β-1b is in solution, other techniques are required to determine the aggregation state of the protein. It is important to determine whether a protein is monomeric in a given formulation and to

5   determine how much of the protein (if any) exists in higher ordered forms such as dimers, trimers, etc. Analytical ultracentrifugation is one of the most powerful techniques for elucidating the aggregation state of proteins (see Liu and Shire (1999) *J. Pharm. Sci.* 88:1237-1241). Three experiments were conducted to characterize the monomeric content of several IFN-β-1b formulations with the use of analytical ultracentrifugation.

10   These analytical ultracentrifugation experiments were each conducted with a different preparation of IFN-β-1b. In this matter, each experiment contained a common formulation (5 mM glycine, pH 3.0). However, each of these common formulations varied slightly in the percent monomer (Figure 3 - 89.8%; Figure 6 - 94.2%; Figure 9 - 86.3%). The recovery and purification procedure used to prepare these IFN-β-1b

15   formulations produces some aggregation of the IFN-β-1b molecule, which is mainly covalent in nature. The 5 mM glycine, pH 3.0 formulation for each experiment therefore serves as the baseline for the amount of aggregate in the formulation at the beginning of each experiment.

The first experiment examined the effect of pH on the IFN-β-1b aggregation state.

20   Formulations at pH 3.0 (containing only 5 mM glycine to buffer the solution), pH 4.0 (containing only 5 mM aspartic acid to buffer the solution), and pH 5.0 (containing only 5 mM sodium succinate to buffer the solution were analyzed. Results are shown in Figures 3, 4 and 5. The main peak in these profiles corresponds to molecular weight of approximately 20 kDa, which is very close to the molecular weight of IFN-β-1b (19.878

25   kDa). The main peak is therefore the IFN-β-1b monomer. Larger species (dimers, trimers, etc.) correspond to higher sedimentation coefficients. These results show that while IFN-β-1b is mainly monomeric at pH 3.0 and pH 4.0 (about 90%), at pH 5.0 the molecule begins to aggregate into higher ordered species and is only about 75% monomeric. These results indicate that the aggregation state of IFN-β-1b is susceptible to

changes in pH, and that the IFN-β-1b monomer is favored by low pH conditions such as pH 3.0 and pH 4.0.

The second experiment investigated the effect of ionic strength on the IFN-β-1b aggregation state. The ionic strength of the formulation was increased in formulations at pH 3.0 (buffered with 5 mM glycine) by adding 0, 50 mM, and 150 mM sodium chloride. Results are shown in Figures 6, 7, and 8. For the formulation containing no added sodium chloride (Figure 6), the monomeric form of IFN-β-1b comprises about 94% of the total IFN-β-1b (i.e., 94% main peak). When 50 mM sodium chloride is added to the formulation, the monomer content drops to about 76% (Figure 7), and with 150 mM sodium chloride in the formulation, the monomer drops to less than 10% (Figure 8). These results indicate that the aggregation state of IFN-β-1b is strongly susceptible to ionic strength and that IFN-β-1b monomer is favored by low-ionic-strength conditions.

A desirable characteristic of an injectable pharmaceutical formulation is that it should be isotonic with body fluids. Ionic substances (such as sodium chloride) and non-ionic substances (such as the sugars sucrose and trehalose) may be used to make the formulation isotonic with body fluids. The previous analytical ultracentrifugation experiments examined formulations that were either not isotonic (containing only 5 mM buffer) or contained sodium chloride as an ionic tonicifier. A third experiment examined the effect of non-ionic tonicifying agents on the aggregation state of IFN-β-1b. In this experiment three formulations at pH 3.0 (buffered with 5 mM glycine) were prepared. One contained only the glycine buffering agent, the second was tonicified with 9% sucrose, and a third was tonicified with 9% trehalose. Analytical ultracentrifugation results are shown in Figures 9, 10, and 11. The monomer content of the formulation with the buffering agent only (Figure 9) is about 86%. When adding either sucrose (Figure 10) or trehalose (Figure 11) as the tonicifying agent, the monomer content is about 89%. These results indicate that non-ionic tonicifying agents such as sucrose and trehalose do not promote aggregation of the IFN-β-1b molecule.

Example 3 - Stability of Lyophilized IFN-β-1b HSA Free Formulations under

Accelerated Temperature Conditions

HSA-free formulations of IFN-β-1b at pH 3.0 (5 mM glycine as buffer) and pH

4.0 (5 mM aspartic acid as buffer) containing either 9% trehalose (pH 3.0 and pH 4.0) or

5   9% sucrose (pH 4.0) were lyophilized. The lyophilized formulations were then stored at

40°C and their stability measured over 8 weeks. Sucrose and trehalose are typical

stabilizing agents used in lyophilized formulations. A level of 9% of these reagents is

used so that the reconstituted formulation will be isotonic with body fluids. To minimize

the ionic strength of the formulations and thus the amount of aggregated IFN-β-1b, the

10   amount of buffer was kept to a minimum level. Thus, all buffers were at a concentration

of 5 mM.

The typical storage condition for protein pharmaceutical products is often 5°C.

However, accelerated temperature conditions are often used in formulation studies to

increase the rate of degradation of a particular formulation so that relevant stability data

15   can be collected in a shorter period of time. In this experiment, 40°C was used to attempt

the forced degradation of IFN-β-1b in HSA-free formulations. Results for concentration

measurements and reverse-phase HPLC (RP-HPLC) analysis are shown in Figures 12

and 13. These results show that even at elevated temperatures, these IFN-β-1b

formulations show no detectable changes over the 8-week study.

20

Example 4 - Stability of Lyophilized IFN-β-1b HSA-Free Formulations Containing

Trehalose Under Real Time Storage Conditions

Although a typical storage condition for protein pharmaceuticals is 5°C, it is

desirable to have a product with room temperature stability (25°C to 30°C). In this

25   experiment, formulations containing 9% trehalose (5 mM glycine, pH 3, or 5 mM

aspartic acid, pH 4) were lyophilized. A concentration of 9% trehalose was used so that

the reconstituted formulation would be isotonic with body fluids. Formulations were

stored at 5°C and 30°C and their stability measured over 9 months. Results for

concentration measurements and reverse-phase HPLC (RP-HPLC) analysis are shown in

Figure 14 and Figure 15. These results show that even at 30°C, these IFN-β-1b formulations show no detectable changes over the 9 months of the study.

Example 5 - Stability of Liquid IFN-β-1b HSA-Free Formulations Under Accelerated Temperature Conditions

The stability of HSA-free formulations of IFN-β-1b at pH 3.0 and pH 4.0 were also examined in the liquid state. The composition of the formulations were the same as outlined in Example 3 (9% trehalose (pH 3.0 and pH 4.0) or 9% sucrose (pH 4.0)). Again, to minimize the ionic strength of the formulations and thus minimize the amount of aggregated IFN-β-1b, the amount of buffer was kept to a minimum level (5 mM). Liquid formulations were stored at 30°C and their stability measured over 9 weeks. The typical storage condition for liquid protein formulations is 5°C. Therefore, 30°C storage represents accelerated temperature conditions designed to increase the rate of IFN-β-1b degradation. Results shown in Figure 16 (concentration measurements) and Figure 17 (reverse-phase HPLC analysis) show no detectable changes in the formulations over the 9-week study. These results indicate that in these formulations under these conditions, the IFN-β-1b is stable over the course of the study.

Example 6 - Stability of Liquid IFN-β-1b HSA Free Formulations Under Real Time Storage Conditions

In this experiment, liquid formulations containing 9% trehalose (5 mM glycine, pH 3, or 5 mM aspartic acid, pH 4) or 9% sucrose (5 mM glycine, pH 3 or 5 mM aspartic acid, pH 4) were examined under real time storage conditions of 5°C. Formulations were filled into vials and their stabilities measured over 9 months. Results for concentration measurements and reverse-phase HPLC (RP-HPLC) analysis are shown in Figure 18 and Figure 19, respectively. These results indicate that the IFN-β-1b in these formulations is stable during the 9 months of this study.

Example 7 - Trehalose is Preferable to Sucrose as a Non-Ionic Tonicifying

Agent for IFN-β-1b Formulations

In this experiment, formulations containing 9% trehalose (5 mM glycine, pH 3, or

5 mM aspartic acid, pH 4) and 9% sucrose (5 mM glycine, pH 3, or 5 mM aspartic acid,

5   pH 4) were prepared and filled into vials as a liquid, and vials of the same formulation

were lyophilized. Their stabilities were measured under accelerated temperature

conditions, which are often predictive of the rank order stability of formulations of a

given protein. Liquid formulations were stored at 30°C for 9 weeks, and lyophilized

formulations were stored at 40°C for 8 weeks. Results of concentration measurements

10   are shown in Figure 20 (liquid) and Figure 21 (lyophilized). These results indicate that

formulations at pH 3 containing sucrose show an apparent increase in concentration.

This apparent increase in concentration is due to the hydrolysis of sucrose at low pH to

form reducing sugars, which results in non-enzymatic browning (i.e., maillard reaction)

of the formulations. Trehalose is much more resistant to hydrolysis, and it is therefore

15   preferred over sucrose in these formulations (see, O'Brien (1996) *Science* 61:679-682).

Example 8: Removal of SDS and Formulation of IFN-β-1b Using

Guanidine Hydrochloride Precipitation

Purified IFN-β-1b (1 L of 1.91 mg/ml in 0.4% SDS, 50 mM acetate buffer, pH

20   5.5) was stored at 5°C. During storage, some of the SDS present precipitated. 250 ml of

this material (477.5 mg) was mixed with 229 g of guanidine hydrochloride (6 M, total

volume 400 ml) and stirred at room temperature for 15 minutes using a magnetic stir bar.

The 6 M guanidine hydrochloride/protein solution was then filtered with a Sartobran® P

Capsule (0.45μm pore size) to remove the precipitated SDS. The protein concentration

25   as determined by UV at 280 nm was 1.02 mg/ml. The protein yield was 406 mg or 85%.

The 400 ml guanidine-hydrochloride treated material was concentrated utilizing a

Millipore® Labscale® TFF diafiltration system (Millipore, Inc.) with two Pellicon® XL

Biomax® 0.1 cm^2 10 kD polysulfone membranes (Millipore, Inc. The volume following

the concentration step was 37 ml with a protein concentration of 10.3 mg/ml for a post

30   concentration yield of 381 mg or 93%.

-33-

Using a transfer pipette, 10 ml (103 mg) of the concentrated guanidine hydrochloride/protein solution were gradually added to 590 ml of 5 mM glycine, pH 3.2 solution. The buffer was at a rapid stir using a magnetic stir bar; the protein solution was added directly to the vortex. This 60X dilution of the 6 M guanidine

5   hydrochloride/protein solution yielded a 0.1 M guanidine hydrochloride/protein solution at 0.17 mg/ml. This 600 ml was transferred to a 500 ml scale diafiltration unit equipped with two Pellicon® II 10kD, 0.1 m^2 polysulfone membranes. This solution was initially concentrated to ~400mL to a protein concentration of 0.23 mg/ml, and subsequently diafiltered against 9 volume changes (3.6 L) of 5 mM glycine at pH 3.2. The final

10   diafiltrate (402 ml) was measured by UV at 280 nm for a final protein concentration of 0.23 mg/ml with a 92.46 mg or 90% yield for the diafiltration step and an overall yield of 72% soluble protein for the purification process.

Example 9 - Stability of Liquid IFN-β-1b HSA Free Formulations

15   Containing Mannitol as the Tonicifying Agent

In this experiment, liquid formulations containing 5 mM aspartic acid, 5% mannitol were examined under real-time storage conditions of 5°C. Three separate preparations (designated Prep A, Prep B, and Prep C in the figures) were prepared from a single lot of HAS-free IFN-β-1b and filled into vials. The vials were stored at 5°C, and

20   the stability of the formulations was measured over 6 months. Results for concentration measurements and reverse-phase HPLC (RP-HPLC) analysis are shown in Figure 22 and Figure 23, respectively. Results demonstrate that no detectable changes occur in these IFN-β-1b formulations over the 6-month study.
